Abstract:	<p>In the present study, 151 third-grade Hong Kong children participated in two expression-picture matching experiments (a relation priming paradigm). In this paradigm, an unambiguous prime was first presented, followed by an ambiguous target that could be interpreted with either of two relations (i.e., Descriptor and Possessor). Children were asked to judge which picture matched with the compounds in both the prime and target sessions. The linear mixed model (LMM) analysis was applied to investigate the semantic relation processing in novel ambiguous combination and its relationship with children's performances on morphological awareness tasks. In Exp. 1, the relation priming effect (i.e., children preferred to select the target pictures involving the same relation with the primes) was observed. At the same time, children's morphological awareness showed a positive moderation effect on relation priming. Exp. 2 investigated whether visual features, rather than semantic relations, produced priming effect. The interaction between semantic relation processing and morphological awareness was observed as well in the situation that the hints of visual features were removed. The results indicated that children with skilled morphological awareness, but not the children with less skilled morphological awareness, showed significant relation priming effect, even without the visual cues. Compared to children with less skilled morphological awareness, children with skilled morphological awareness were better in activating semantic relation information when reading compounds. These findings may help us understand the mechanism of the association between MA and Chinese literacy acquisition.</p>	
Response to Reviewers:	<p>Response to the reviewers</p> <p>Reviewer #1: Review for MS# READ-D-17-00253 In this study, the authors examined the question of whether the semantic relation priming effect existed in third-grade Hong Kong Chinese children by using the</p>	

expression-picture matching paradigm. They further investigated whether such an effect was influenced by morphological awareness. Results revealed that children with good morphological awareness (MA) had a better performance in semantic relation information processing when reading compounds.

In general, this is a paper with interesting research questions relevant to compound reading. The methodology was solid. However, there are some issues needed to reconsider or clarify.

1. My first concern is about the vocabulary of the two groups. If there is any formal assessment of vocabulary in the two groups.

Response: We did not assess children's vocabulary, however, we tested participants' Chinese character reading, and treated their performance of Chinese character reading as the covariate in the data analysis. The performance of Chinese character reading could be an indicator of children's reading at word level. On the other hand, based on the design of the current study, all the stimuli are novel combinations. These novel combinations do not have a close relationship with the daily life vocabulary. Moreover, the nouns in the novel combinations are simple character with high frequency. The novel combinations are presented with the corresponding picture and audio. In other words, the influence of children's vocabulary on the processing of the novel combinations has been well controlled in the present study.

2. My second major concern is about the data analysis. The authors used a grouping design with ANOVA. Whether analyses such as correlation, regression and mediating effect could be used given that the main purpose of this study to examine the relation between MA, semantic relation information processing and compound word reading?

Response: Thanks for your suggestion. In the revised manuscript, we utilize the linear mixed model to study whether the priming effect of semantic relation is significant in Chinese children's word comprehension and the possible relationship between semantic relation processing and children's morphological awareness. By using the linear mixed model, the data from more participants were been involved (the former ANOVA design only included 48 participants, the linear mixed model analysis included 151 participants) and more factors were taken into account. In details, in the models, the proportion of corresponding pictures selected for the target combination was considered as the DV, while the consistency of semantic relation in the prime-target pairs and children's performance of morphological awareness were considered as IVs. At the same time, the models include children's age, non-verbal intelligence, scores of Chinese character reading and phonological awareness, and the frequency and the complexity of the items, as controls. The results were similar with the ANOVA results. To illustrate, both in the concurrent and longitudinal models in Exp.1, the main effect of semantic relation priming and its interaction with morphological awareness were significant ($p < .01$). In Exp.2, the main effect of semantic relation priming was not significant either in the concurrent or the longitudinal model. However, the interaction between semantic relation priming and morphological awareness was significant in both the concurrent and longitudinal models ($p < .05$). In other words, morphological awareness significantly moderated that semantic relation priming effect, even without the visual cues.

3. Although the expression-picture matching paradigm was advanced, the key result lies in a marginally significant interaction between Priming relation and MA group ($p=0.07$) in experiment 2, with a very weak effect ($\eta^2=0.07$). The data do not provide convincing support for the authors' conclusion. One reason for this might be the small sample size. And there might be a big variation across individuals in children study. The data is thus very difficult to interpret, and might be insufficient for a stand-alone publication.

Response: Thanks for your suggestion, as mentioned before, we utilized the linear mixed model for the data analysis. The results of the linear mixed models of Exp. 1 and Exp. 2 are similar with the results from the ANOVA design. By enlarging the sample size from 48 to 151, we found that the interaction between semantic relation priming and children's morphological is significant rather than marginally significant.

4. What is the role of reading experience? Whether the authors selected children with

poor and good CCR using a similar grouping design and examined whether there was a group difference in the semantic relation information processing?

Response: As mentioned before, we conducted the linear mixed effect models for the data analysis. In order to control the influence of Chinese character reading on the interaction between semantic relation priming and morphological awareness, we treated it as the fixed factor. The results showed that both in the concurrent and longitudinal models of Exp.1 and Exp.2, the main effect of Chinese character reading was not significant ($p > .05$).

Reviewer #2: The manuscript is well organized. However I think it has two weakness:
1. The study does not show the novelty. Many studies have showed the positive relationship between morphological awareness and semantic processing in this area. It is not convincing what the knowledge gap is and what the novelty is in this study.

Response: We agree that a number of previous studies have tapped the relationship between morphological awareness and vocabulary and/or reading comprehension in Chinese that are related to the “semantic processing” mentioned in this comment. However, on the one hand, what we focus on in the present study is “semantic relation processing”, rather than “semantic processing”. The former is about the processing of the detailed internal semantic relation of the constituent morphemes of compounds, while the latter is a general term about processing of semantic information. On the other hand, to our knowledge, there have been none studies in either Chinese or alphabetic languages that tapped the relationship between morphological awareness and semantic relation processing, and very few, if any, investigated the semantic relation processing in children. As we mentioned in the manuscript, such a study is interesting because it can help us understand the relationship between morphological awareness and semantic relation processing, and more importantly help us understand the mechanism of the role of morphological awareness in facilitating the learning of compounds in Chinese. Moreover, the results of the current study could also provide some practical suggestions for the children with poor morphological awareness. We found that the visual features could be an effective cue for children to understanding the novel words. With the help of the visual feature, children with less developed morphological awareness could perform as good as the children with more developed morphological awareness. All these could be the evidence of the novelty and significance of the present study.

2. The study design is short of validity. The researchers manually selected good and poor MA group, and examined the relationship with semantic processing in Chinese. The relationship is more intended to be significant. Why do not use the scores of morphological tasks instead?

Response: Thanks for your suggestion. In the revised manuscript, we use the scores of morphological tasks instead of dividing participants into two groups based on their morphological awareness. In addition, we utilize the linear mixed model for the data analysis, which allows all random factors to be considered simultaneously with fixed effects. By using the linear mixed model, the numbers of the participants is enlarged from 48 to 151. We constructed the linear mixed effect models for investigating the relationship between semantic relation priming effect and children’s morphological awareness (we applied the scores of the morphological awareness tasks as the index). At the same time, the models include children’s age, non-verbal intelligence, scores of Chinese character reading and phonological awareness, the frequency and the complexity of the items. The results were similar with the ANOVA design. To illustrate, both in the concurrent and longitudinal models in Exp.1, the main effect of semantic relation priming and its interaction with morphological awareness were significant ($p < .01$). In Exp.2, the main effect of semantic relation priming was not significant either in the concurrent or the longitudinal model. However, the interaction between semantic relation priming and morphological awareness was significant in both the concurrent and longitudinal models ($p < .05$). In other words, morphological awareness significantly moderated that semantic relation priming effect, even without the visual cues.

The Relationship between the Processing of Semantic Relation Information and
Morphological Awareness among Hong Kong Chinese Children

Kong in Hong Kong Special Administrative Region. We thank all the children, their parents
and teachers, for their participation.

This is the pre-published version.

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 1

Abstract

In the present study, 151 third-grade Hong Kong children participated in two expression-picture matching experiments (a relation priming paradigm). In this paradigm, an unambiguous prime was first presented, followed by an ambiguous target that could be interpreted with either of two relations (i.e., Descriptor and Possessor). Children were asked to judge which picture matched with the compounds in both the prime and target sessions.

The linear mixed model (LMM) analysis was applied to investigate the semantic relation processing in novel ambiguous combination and its relationship with children's performances on morphological awareness tasks. In Exp. 1, the relation priming effect (i.e., children preferred to select the target pictures involving the same relation with the primes) was observed. At the same time, children's morphological awareness showed a positive moderation effect on relation priming. Exp. 2 investigated whether visual features, rather than semantic relations, produced priming effect. The interaction between semantic relation processing and morphological awareness was observed as well in the situation that the hints of visual features were removed. The results indicated that children with skilled morphological awareness, but not the children with less skilled morphological awareness,

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 2

1 showed significant relation priming effect, even without the visual cues. Compared to
2
3
4
5 children with less skilled morphological awareness, children with skilled morphological
6
7
8 awareness were better in activating semantic relation information when reading compounds.
9

10
11
12 These findings may help us understand the mechanism of the association between MA and
13
14
15
16 Chinese literacy acquisition.

1 The Relationship between the Processing of Semantic Relation Information and
23
4
5 Morphological Awareness among Hong Kong Chinese Children
6

7
8 Current research has found that morphological awareness, namely the ability to reflect
9
10 upon and manipulate morphemes and apply word formation rules in one's language (Carlisle,
11
12 2000), contributes to word reading in both alphabetic languages (e.g., Ku & Anderson, 2003,
13
14 Mahony, Singson & Mann, 2000) and Chinese (e.g., Li, Anderson, Nagy, & Zhang, 2002; Liu
15
16 & McBride-Chang, 2010; McBride-Chang, Shu, Zhou, Wat & Wagner, 2003). However, as
17
18 indicated by some researchers, currently the mechanisms underlying their association is still
19
20 not very clear (Carlisle, 2010; McCutchen & Stull, 2015).
21

23
24
25
26
27
28
29
30
31
32
33

34 At the same time, there is evidence from English studies that the recent usage of
35
36 semantic relation information, i.e., a relation structure linking the compound's constituents
37
38 (Schmidtke, Kuperman, Gagné, & Spalding, 2016), could influence the way adults process
39
40 novel compounds (Raffray, Pickering, & Branigan, 2007). The results demonstrated that
41
42 adults could apply semantic relation information in a prime compound to help understand a
43
44 subsequent novel conceptual combination in expression-picture matching tasks. It should be
45
46 noted that in addition to the semantic relations, the morphological structure of compounds
47
48
49
50
51
52
53
54
55

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 4

1 also plays a role in connecting morphemes and constructing meaning. In this study, we
2
3
4
5 examined whether Chinese children's morphological awareness could facilitate the
6
7
8 processing of semantic relation information when processing novel compounds, in order to
9
10
11
12 investigate the mechanism underlying the association between morphological awareness and
13
14
15
16 Chinese word reading.

17
18
19
20 It was believed that one reason why morphological awareness is important for word
21
22
23 reading is that it could help children analyse morphologically complex words that follow the
24
25
26 morphological rules (Nagy & Anderson, 1984; Tyler & Nagy, 1990). For example, in view of
27
28
29 derivational morphology, children could know that the word *happiness* is a noun because
30
31
32
33
34
35 *ness* is a suffix that indicates the word class as a noun. Knowing some root morphemes and
36
37
38 the functions of some affixes would help children understand the meaning of many complex
39
40
41
42 words.

43
44
45
46 However, when it comes to compound words, analysing the morphological structure
47
48
49 may not be adequate for accurate comprehension. For example, when processing the word
50
51
52
53 *cupboard*, knowing that *cup* is a modifier and *board* is a head, and thus this is a modification
54
55
56
57 structure, may be not enough for accurate understanding of the semantic content. On top of
58
59
60
61
62
63
64
65

1 specifying the morphological role of each constituent, one also needs to posit a specific
2
3
4
5 connection between the constituents for an accurate understanding (e.g., the word *cupboard*
6
7
8 should be understood as a *board* for storing *cup*, rather than a *board* made of *cups* or a *board*
9
10
11
12 belonging to a *cup*). The processing of semantic relation information is required to provide
13
14
15
16 the additional information above and aid access to meaning (Schmidtke et al., 2016).
17
18
19

20 Some empirical findings supported the importance of semantic relation information in
21
22
23 word processing. For example, Coolen, van Jaarsveld, and Schreuder (1991) found that it
24
25
26
27 took a longer time for Dutch adults to correctly respond to novel compounds (with the same
28
29
30 morphological structure, i.e., subordinate) that involve semantic relations rated as highly
31
32
33
34 interpretable (e.g., flu season), while a shorter reaction time was recorded in trials that
35
36
37
38 involve semantic relations rated as less interpretable (e.g., soil key). They demonstrated that
39
40
41
42 the processing of nominal compounds was not solely affected by the grammatical features
43
44
45
46 (i.e., modifier and head) of the compound, but also by semantic relations.
47
48

49 There might be a close relationship between morphological awareness and semantic
50
51
52
53 relation processing in Chinese because more than 75% of Chinese words are compounds (Sun,
54
55
56
57 Sun, Huang, Li, & Xing, 1996), which are formed by combining two or more bound or free
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 6

1 morphemes. In addition, a great number of Chinese compound words are semantically
2
3
4 transparent, which means that the meaning of each constituent morpheme contributes directly
5
6
7
8 to the meaning of the compound (Chen, Hao, Geva, Zhu, & Shu, 2009). For instance, the
9
10
11 compound word 房門/fong4 mun4/ (door of house), a combination of the morphemes 房
12
13 /fong4/ (house) that means house and 門/mun4/ (door) that means door. In addition to the
14
15
16 morphological information, which is that 房/fong4/ (house) is a modifier and 門/mun4/ (door)
17
18
19 is the head, the information about how the constituents are linked semantically (i.e., semantic
20
21
22 relation) also plays a critical role in determining the meaning of the whole compound.
23
24
25
26
27
28
29
30

31 Also, semantic relation information may help Chinese children distinguish between
32
33
34 similar compounds. For example, for subordinate compounds constructed with the morpheme
35
36
37 房/fong4/ (house) as a modifier, possible combinations include 房門/fong4 mun4/ (door of
38
39 house) or 房車/fong4 ce1/ (recreational vehicle). Based on the semantic relation knowledge,
40
41
42 children could figure out that in the compounds 房門/fong4 mun4/ (door of house) and 房車
43
44
45 /fong4 ce1/ (recreational vehicle) the same modifier 房/fong4/ (house) is related to 門
46
47
48 /mun4/ (door) and 車/ce1/ (car) in distinctive ways. The former compound contains the
49
50
51
52
53
54
55
56
57 POSSESS relation (house POSSESS door); while the later compound involves the
58
59
60
61
62
63
64
65

1 DESCRIBE relation (house DESCRIBE car).
2
3
4

5 In the present study, therefore, we proposed that morphological awareness might
6
7
8 facilitate the processing of semantic relation information. Both the processing of
9
10
11
12 morphological information and of semantic relation involve the insight into the internal
13
14
15 structure of compound words. In other words, both are about how the constituent morphemes
16
17
18 are connected with each other in contributing to the overall meaning of the whole compound.
19
20
21
22
23 However, they work at different levels. Morphological structure information could only
24
25
26 convey the general type of the association between the morphemes (such as subordinate or
27
28
29 coordinative), while the semantic relation information could inform of more fine details about
30
31
32 the association (e.g., whether the modifier describes or possesses the head in a subordinate
33
34
35 compound). In other words, morphological information could facilitate the approximate
36
37
38 understanding of words (McCutchen & Logan, 2011), whereas semantic relations could aid
39
40
41
42
43
44
45 access to the exact meaning of the compounds (Schmidtke et al., 2016).
46
47
48

49 Taken together, we proposed that awareness of morphological structure should be the
50
51
52 foundation of analyzing semantic relations. Although there is a lack of empirical evidence to
53
54
55
56
57 support this hypothesis, it has been found that knowledge of semantic relations was acquired
58
59
60
61
62
63
64
65

1 later than that of morphological information among children (Nicoladis, 2003). The
2
3
4
5 processing of semantic relation information has been observed in a series of relation priming
6
7
8 studies (e.g., Estes, 2003; Estes & Jones, 2006; Gagné, 2000, 2001; Gagné & Shoben, 2002).
9
10
11
12 For example, Gagné (2001) found that after seeing a prime, such as *wood spoon*, which is a
13
14
15 spoon made of wood (MADE OF relation), participants responded faster to compounds with
16
17
18 the same relation, such as *glass cup* than to compounds with a different relation, such as *book*
19
20
21 *shelf* (FOR relation, a *shelf* FOR *books*).
22
23
24

25
26
27 This relation priming effect was observed not only in real compounds, but also in
28
29
30 novel ones (Raffray et al., 2007). Compared with real compounds, the semantic relations in
31
32
33 novel compounds are relative unconstrained. To illustrate, in established real compounds like
34
35
36 *tea cup*, the widely accepted semantic relation between the morphemes is FOR, and therefore
37
38
39 it should be interpreted as a cup FOR tea. However, an ambiguous and novel combination
40
41
42 such as *cake cup* can be interpreted either as *a cup for cake* (FOR relation) or *a cup made of*
43
44
45 *cake* (MADE OF relation).
46
47
48
49
50
51

52
53 Raffray et al. (2007) utilised the expression-picture matching paradigm to investigate
54
55
56
57 the relation priming effect in adults. In this paradigm, participants were first presented with a
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 9

1 prime expression that could be interpreted as involving either one of two possible relations
2
3
4
5 (POSSESSOR, i.e., the modifier possesses the head; and DESCRIPTOR, i.e., the modifier is
6
7
8 a feature of the head and thus can describe it). Then, they were presented with two pictures
9
10
11
12 and were asked to choose an appropriate picture for the prime combination. One picture
13
14
15
16 matched one of the two relations (i.e., POSSESSOR or DESCRIPTOR), while the other
17
18
19
20 picture matched neither. The participants were then presented with a target combination that
21
22
23
24 could be plausibly interpreted as involving either of the two relations. Afterwards, the
25
26
27
28 participants were shown two pictures, each expressing one of the two relations. The
29
30
31
32 participants were asked to select one among the two pictures that could represent the target
33
34
35
36 expression as quickly and as accurately as possible.

37
38 The results illustrated that participants preferred to choose target pictures involving
39
40
41
42 the same semantic relation as the prime compound, regardless of whether the morphemes are
43
44
45
46 repeated between the prime and the target. The findings posited that adults (expert readers)
47
48
49
50 have an ability to process and apply the semantic relations in novel compounds: when facing
51
52
53
54 with the novel compounds that have the same form as the preceding one, they would rely on
55
56
57
58 the recent usage of semantic relation to access the meaning of the new compounds.
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 10

1 To date, semantic relation processing has been scarcely studied in Chinese children.
2
3

4
5 Therefore, it was one purpose of the present study to examine whether the semantic relation
6
7
8 priming effect could be found in third-grade Hong Kong Chinese children. More importantly,
9
10
11
12 we also would like to investigate whether morphological awareness could facilitate the
13
14
15
16 processing of semantic relation information in compounds.
17
18
19

20 To focus on the process of learning novel compounds and to reduce the influence of
21
22
23 past experience and knowledge, the expression-picture matching paradigm (Raffray et al.,
24
25
26
27 2007) was adopted in the present study. Using novel combinations along with pictures could
28
29
30
31 render the test more interesting and thus more suitable for children. To ease children's
32
33
34
35 comprehension of the items, the compounds were presented both visually and aurally.
36
37
38 Besides, to avoid the lexical priming effect, repetition of lexical items had been avoided in
39
40
41
42 the prime-target pairs.
43
44
45

46 We used the same semantic relations included in Raffray et al. (2007), which are also
47
48
49 common in Chinese: POSSESSOR (i.e., the modifier possesses the head, e.g., “狗糧”, /gau2
50
51
52 uk1/ dog food, the dog possesses the food) and DESCRIPTOR (i.e., the modifier describes
53
54
55
56 the head, e.g., “毛筆”, /maau4 bat1/ writing brush, the brush describes the pen). Each
57
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE 11
CHILDREN

1 ambiguous target compound could be plausibly interpreted based on either of the two
2
3
4
5 relations. For example, the combination “豬書” (/zyu1 syu1/ pig book) could be interpreted
6
7
8 as “a book possessed by a pig” or “a book with a pig picture on it” (as shown in Figure 1).
9

10
11
12 [Insert Figure 1 here]
13
14
15

16 We selected third-grade students as subjects, since this population’s lexical knowledge
17
18
19 is fairly well developed but not yet reach the ceiling (Carlisle, 2000). Based on previous
20
21
22 studies, we conducted two tasks to test children’s morphological awareness: homograph
23
24
25 awareness task and compounding production task (Liu, Li, & Wong, 2017). The following
26
27
28 variables were included as controls: age, nonverbal intelligence, phonological awareness, and
29
30
31 Chinese character reading. Phonological awareness was found to be closely related to
32
33
34 morphological awareness (McCutchen & Logan, 2011). By controlling it, we could minimize
35
36
37 the possibility that the effect we observed from morphological awareness is due to the
38
39
40 influence of phonological awareness. On the other hand, Chinese character reading is not
41
42
43 only related to morphological awareness (e.g., Ku, & Anderson, 2003; McBride-Chang et al.,
44
45
46 2003), but might also be associated with the responses to the prime and target compounds.
47
48
49
50
51
52
53
54
55
56
57 Thus, we included it as a covariate.
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 13

1 participants completed the tasks for morphological awareness, phonological awareness, and
2
3
4
5 Chinese character reading at both Times 1 and 2.
6
7

8 ***Morphological awareness.*** Homograph awareness task and compounding production
9
10
11
12 task were used to test children’s morphological awareness (Liu et al, 2017).
13
14
15

16 *Homophone awareness task.* Children were first presented with a target word and then
17
18
19
20 were asked to select from three words the one that shared “a character that had the same
21
22
23 meaning” (i.e., the same morpheme) as the target word. For example, 商量 (soeng1 loeng4,
24
25
26 consult) was the target word, while 商店 (soeng1 dim3, store) and 商定 (soeng1 ding6,
27
28
29 agree) were the two options. The correct answer is 商定 (agree). There were totally 32 items
30
31
32 in this task and all of them were presented orally. One point was given for a correct answer,
33
34
35
36 and thus the maximum score was 32. The Cronbach’s alpha was .82.
37
38
39
40
41

42 *Compounding production task.* Children were presented with a scenario, and asked to
43
44
45
46 create a novel word to properly represent the scenario. For example, one item in this task was
47
48
49 “我們把專門吃鐵的怪獸叫做什麼? (How should we call a monster that can only eat iron?)”
50
51
52
53 The answer for this item was 吃鐵怪 (iron-eating monster). Children’s answers were rated
54
55
56
57 based on a five-point scale (0-4). There were totally 31 items in this task, and thus the
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 14

1 maximum score was 124. All the items were orally presented. The Cronbach's alpha was .86.

2
3
4
5 *Expression-picture matching task.* The materials consisted of 32 item sets. Each item
6
7
8
9 set contained a prime trial and a target trial. Each trial consisted of a compound, its
10
11
12 corresponding audio, and two pictures. The compound always comprised an animate noun as
13
14
15 the first constituent and a non-animate noun as the second constituent. The average frequency
16
17
18 of all the constituents of the compounds was 167.46 (Poon & Hong, 2003), and thus all
19
20
21 characters are of high frequencies. All Chinese words were presented in black on a gray
22
23
24 background with a font size of 18 in Microsoft JhengHei. A college student majoring in
25
26
27 Visual Arts created the picture stimuli. All pictures were presented with a white background
28
29
30
31 at a size of about 400 x 564 pixels.
32
33
34
35
36
37

38 For the pictures in the prime condition, one of the pictures was a matching picture that
39
40
41 depicted either a POSSESSOR or a DESCRIPTOR relation in the compound, and the other
42
43
44 picture was a non-matching picture that depicted either the head or the modifier of the
45
46
47 compound word but not both. For instance, “鯊碗” (/saa1 wun2/, shark bowl) was presented
48
49
50 with a matching picture showing a shark holding a bowl and a distractor showing an elephant
51
52
53 holding a bowl.
54
55
56
57
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE 15
CHILDREN

1 In the target condition, however, both of the presented pictures could be semantically
2
3
4
5 related to the compound. One picture depicted the POSSESSOR relation, whereas the other
6
7
8 depicted the DESCRIPTOR relation. For instance, the compound “豬書” (/zyu1 syu1/ pig
9
10 book) could be depicted as a pig holding a book or a pig on the cover of a book, as shown in
11
12
13
14
15
16 Figure 1. Each target was preceded by two distinct primes with different relation
17
18
19 interpretations, one at a time. To avoid repetitive priming, each prime-target pair shared
20
21
22
23 neither the same head nor the same modifier. In total, each relation condition consisted of 16
24
25
26
27 item sets.

28
29
30 The experiment also contained 64 fillers. Each filler contained a two-character word,
31
32
33
34
35 its corresponding audio, and two pictures. As in the prime condition, the filler trials consisted
36
37
38 of a matching picture and a non-matching picture. The two-character combination in the filler
39
40
41 conditions could be a singular word (e.g., 相機/soeng3 gei1/ camera) or a compound (e.g.,
42
43
44 狐豹/wu4 paau3/ fox leopard), both of which were constructed by either animate or
45
46
47
48 non-animate items. In other words, all compounds were combined with either two animate or
49
50
51 two non-animate constituents.
52
53
54

55
56
57 The experiment was conducted in a quiet room. The participants were asked to seat in
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE 16
CHILDREN

1 front of a computer screen, and E-prime was used to present the stimuli and collect the data.
2
3

4
5 After reading the instructions, the participants were required to finish 8 practice trials before
6
7

8 the experimental trials began. All practice trials used the filler items. Feedback was given
9

10
11
12 after the participants finished each practice trial, but no feedback was given in the
13
14

15
16 experimental trials.
17
18

19
20 One trial started with the presentation of a fixation cross at the centre of the screen for
21

22
23 250ms, with a “beep” sound to remind the participant that the test was about to start. After a
24
25

26
27 blank screen presented for 500ms, a compound appeared at the centre of the screen for
28
29

30
31 1200ms. Simultaneously, the participant heard the corresponding pronunciation. Then, after
32
33

34
35 another blank screen was shown for 500ms, two pictures appeared on the left and right part of
36
37

38 the screen. Once the pictures appeared, the participants were allowed to respond by pressing
39
40

41
42 the “F” key on the keyboard to choose the picture on the left or the “J” key for the picture on
43
44

45
46 the right. They were encouraged to make judgments as quickly and as accurately as possible.
47
48

49
50 The experimental procedure is illustrated in Figure 2.
51

52
53 [Insert Figure 2 here]
54
55
56
57
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 17

1 In total, the participants underwent 8 trials for the practice session and 128 trials (32
2
3
4
5 primes, 32 targets, 64 fillers) for the formal test. Two fillers were presented after each
6
7
8
9 prime-target pair, and each relation would not appear sequentially more than three times.
10
11
12 Moreover, the same target would not appear twice successively. The whole task lasted for
13
14
15
16 about 15 minutes for each participant.
17

18
19 ***Raven's standard progressive matrices.*** Raven's Standard Progressive Matrices
20
21
22
23 (Raven, 1996) is a non-verbal multiple-choice measure of children's reasoning ability. Sets A
24
25
26
27 and B were administered to measure young children's nonverbal reasoning. There are 24
28
29
30
31 items, and the maximum score was 24. For each test item, children were asked to identify the
32
33
34
35 missing element that completed a pattern from among six choices. The Cronbach's alpha
36
37
38
39 was .78.
40
41

42 ***Chinese Character reading.*** A Chinese character reading task was used to examine
43
44
45
46 children's reading ability at word level. In this task, children were required to read 3 character
47
48
49
50 lists aloud one by one, each list contained 72 characters and was ordered in ascending
51
52
53
54 difficulty. When children failed to recognise 15 consecutive characters in a list, testing
55
56
57
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 18

1 proceeded to the next list. One point was allocated to each correct answer, and thus the
2
3
4
5 maximum score was 217. The Cronbach's alpha was .98.
6
7

8 ***Phonological awareness task.*** Children's phonological awareness was measured with
9
10 a task consisting of 9 syllable deletion and 22 onset deletion items (McBride-Chang et
11
12 al., 2003). In each syllable deletion item, children were asked to remove a syllable from a
13
14 three-syllable word. For example, say "he6 kou1 peng2" without "kou1," the answer was
15
16 "he6 peng2." In an onset deletion item, children were asked to remove the onset of a syllable.
17
18 For example, say "gut3" without "g," the answer was "ut3." One point will give to each
19
20 correct answer, and thus the maximum score was 31. The Cronbach's alpha was .95.
21

23
24
25
26
27
28
29
30
31
32
33

34 Results

35
36
37
38 Since the main purpose of the expression-picture matching paradigm adopted in the
39
40 present study was to examine the influence of previously processed semantic relation
41
42 information on the interpretation of a subsequent expression rather than the time course of
43
44 comprehension for an ambiguous expression, the dependent measure was the proportion of
45
46 corresponding pictures selected for the target combination rather than the response time. The
47
48 accuracy of responses to the primes, targets, and fillers were recorded. The accuracy on the
49
50
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE 19 CHILDREN

1 prime trials was measured based on whether the participants chose the pictures that reflected
2
3
4
5 a correct interpretation of the combinations. Since both pictures in the target trials reflected a
6
7
8 plausible interpretation of the compounds, responses that matched the relation involved in the
9
10
11
12 corresponding prime were recorded as correct, whereas responses that did not match the
13
14
15
16 relation were recorded as incorrect.

17
18
19
20 Only the target trials with correct responses in the paired prime items were included in
21
22
23 the analyses. On average, the accuracy of responses to the prime and filler trials was 98%. In
24
25
26 total, 4.65% of the data were excluded because children made incorrect responses to the
27
28
29
30 primes. Considering that on the target trials the selection of DESCRIPTOR responses and
31
32
33
34 POSSESSOR responses were two alternatives in each priming condition, and that analysis of
35
36
37 the difference in selection of either type of target between the 2 priming conditions would
38
39
40
41 reflect that of the other, we focused on the difference in the selection of POSSESSOR targets
42
43
44
45 between the two priming conditions (i.e., POSSESSOR primes and DESCRIPTOR primes).
46
47
48
49 The results would have been exactly the same if we selected the difference of the selection of
50
51
52
53 DESCRIPTOR targets for analysis.
54
55
56

57 **Linear mixed model analysis**
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 20

1 With reference to Raffray et al. (2007)'s study, we utilized the linear mixed model
2
3
4
5 (LMM) for further comparison of the response preference. LMM allows all random factors
6
7
8 (i.e., factors of participants and stimuli) to be considered simultaneously together with fixed
9
10
11
12 effects of interests, such as the semantic relation priming effect (i.e., the preference difference
13
14
15 between the trials that involved semantic relations that were consistent and inconsistent with
16
17
18 corresponding primes), morphological awareness, Chinese character reading, and
19
20
21 phonological awareness.
22
23
24
25
26

27 Stepwise regression analyses using the LMM method was adopted to answer two
28
29
30 questions: a) whether the priming effect of semantic relation can be observed in third grade
31
32
33 Chinese children; and b) whether the priming effect of semantic relation can be moderated by
34
35
36 children's morphological awareness. The LMM analyses were conducted using the lmer
37
38
39 program of the lme4 package in R 3.4.2 (R Core Team, 2017); the significance of fixed effect
40
41
42 was assessed using the lmerTest package.
43
44
45
46
47
48
49

50 Response preference of the expression-picture matching task was analyzed by using
51
52
53 the LMM model described below. In order to answer the research questions of the present
54
55
56 study, we created two models. In both models, the consistency of semantic relation in the
57
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 21

1 prime-target pairs (i.e., POSSESSOR-POSSESSOR pair was defined as consistent and
2
3
4
5 DESCRIPTOR- POSSESSOR pair was defined as inconsistent) was specified as the fixed
6
7
8 factor. For investigating the semantic relation priming effect (i.e., the difference between the
9
10
11
12 consistent and inconsistent conditions), we specified the semantic relation contrast by coding
13
14
15
16 the consistent and inconsistent pairs as +0.5 and -0.5 respectively.
17
18
19

20 The first model focused on the concurrent interaction between semantic relation
21
22
23 processing and morphological awareness at Time 2. Thus, morphological awareness, Chinese
24
25
26 character reading and phonological awareness at Time 2 were involved as fixed continuous
27
28
29 factors. The sum of the standard scores of the two morphological awareness tasks were taken
30
31
32
33
34 as an indicator of morphological awareness. In addition, age, non-verbal intelligence, and
35
36
37
38 frequency and visual complexity of stimuli (i.e., the sum of the corresponding values for the
39
40
41
42 first and the second character of the combination) were entered as fixed continuous factors as
43
44
45
46 well. All the continuous variables were centered by z-score transformation of raw scores to
47
48
49 overcome the problem of collinearity. The random factors included the ones that were related
50
51
52
53 to the participants (i.e., individual difference, age, non-verbal intelligence, and the scores of
54
55
56
57 morphological awareness, Chinese character reading and phonological awareness) and the
58
59
60
61
62
63
64
65

1 trials (individual difference in stimuli, the semantic relation condition, the frequency and
2
3
4
5 complexity of stimuli).
6

7
8 The second model examined the interaction between morphological awareness and
9
10
11 semantic relation priming longitudinally by including the measures of morphological
12
13 awareness, Chinese character reading and phonological awareness in Time 1. The results of
14
15
16 the LMM model in Exp.1 are summarized in Table 1.
17
18
19
20
21

22
23 The results of the concurrent LMM model in Exp.1 showed that the main effect of
24
25
26 semantic relation consistency and its interaction with morphological awareness were
27
28
29 significant. Children showed preference for the relation (i.e., POSSESSOR relation)
30
31
32 consistent with the one involved in the prime compound in interpreting the ambiguous target
33
34
35 combination. At the same time, the semantic relation consistency showed a positive
36
37
38 interaction with morphological awareness: the higher the score of morphological awareness
39
40
41
42 tasks, the larger the difference between preference for consistent and inconsistent semantic
43
44
45
46 relations.
47
48
49
50

51
52 Consistent with the results of the concurrent model, the results of the longitudinal
53
54
55 model in Exp.1 showed that the main effect of semantic relation consistency was significant.
56
57
58
59
60
61
62
63
64
65

1 In addition, the interaction between semantic relation consistency and children's performance
2
3
4
5 in morphological awareness at Time 1 was significant. Children with better performance in
6
7
8 the tests for morphological awareness at Time 1 showed a larger priming effect of semantic
9
10
11
12 relation at Time 2.

13
14
15
16 [Insert Table 1 here]

17 18 19 20 **Discussion**

21
22
23 The main effect of semantic relation priming was significant both in the concurrent
24
25
26 and longitudinal LMM models of Exp.1, indicating that these children had the ability to
27
28
29 process internal semantic relations of compounds. They preferred to utilise the semantic
30
31
32 relation that had been used in the prime to interpret the ambiguous novel words.
33
34
35
36

37
38 In addition, the significant interaction between semantic relation priming and
39
40
41 morphological awareness indicated that compared to the children with poor morphological
42
43
44 awareness, a larger semantic relation priming effect was observed in the children with good
45
46
47 morphological awareness. Interestingly, the significant interaction between semantic relation
48
49
50 priming and morphological awareness was observed in both the T2 concurrent model and the
51
52
53
54
55
56
57 T1-T2 longitudinal model.
58
59
60
61
62
63
64
65

1 However, in Exp. 1, since the modifier was visually larger in the POSSESSOR
2
3
4
5 relation, while the head was visually larger in the DESCRIPTOR relation (as shown in Figure
6
7
8
9 1), the interpretation of ambiguous combinations might be influenced by the visual similarity
10
11
12 between the prime and the target. In other words, similar visual features between the prime
13
14
15 and the target might have decreased the difficulty of the task. Apart from using the semantic
16
17
18 relation information, children might rely on visual cues to select answers on the target trials.
19
20
21
22

23 To investigate whether visual features of the stimuli would influence the semantic
24
25
26 relation priming effect, we adopted the design in Raffray et al.'s (2007) study (Exp. 3 in their
27
28
29 study), and modified the prime pictures so that they contained two possible relations at the
30
31
32 same time (as shown in Figure 3). If children relied heavily on the visual features, rather than
33
34
35 using the semantic relation information, in making their judgments, the relation priming
36
37
38 effect would disappear as a result of this modification.
39
40
41
42
43
44
45

46 **Experiment 2**

47
48
49 In Exp.2, we considered the impact of visual similarity, and thus adopted the design in
50
51
52 Raffray et al.'s (2007) study (Exp. 3 in their study) to examine whether the relation priming
53
54
55 effect would remain after controlling for visual similarity of the materials.
56
57
58
59
60
61
62
63
64
65

[Insert Figure 3 here]

Method

Participants. Children who were included in Exp. 1 participated in Exp. 2.

Procedure and materials. Children were asked to complete another expression-picture matching task; the procedure of this task was the same with Exp.1. However, the materials consisted of 16 item sets, which were different from those used in Exp. 1. In each prime trial of Exp. 2, a prime picture and a distractor picture were presented. Each of the pictures involved two semantic relations (i.e., POSSESSOR and DESCRIPTOR) at the same time. For instance, a picture in which a sheep wore a bracelet with a rabbit decoration on it could be interpreted either as “羊環” (/joeng4 waan4/, sheep bracelet) based on a POSSESSOR relation or “兔環” (/tou3 waan4/, rabbit bracelet) based on a DESCRIPTOR relation. The distractor picture depicted one constituent of the word but did not match the complete meaning (e.g., a picture showing a sheep holding a book instead of a bracelet was the distractor picture for “羊環”). The two possible primes (“羊環” or “兔環”), which were depicted by the same picture, were expected to prime for two targets involving different semantic relations (POSSESSOR relation or DESCRIPTOR relation) respectively.

1 The target item, which was similar to that in Exp. 1, included two pictures depicting
2
3
4
5 different interpretations of the target word. For instance, "鼠箱" (/syu2 soeng1/, rat box) was
6
7
8 depicted by 2 pictures depicting a box owned by a mouse (POSSESSOR relation) and a box
9
10
11 with a mouse's image on it (DESCRIPTOR relation) respectively. The response was expected
12
13
14 to be primed by the ambiguous prime picture depicting either "羊環" (depicted POSSESSOR
15
16 relation) or "兔環" (depicted DESCRIPTOR relation). The average frequency of the prime
17
18
19 and target compound words was 135.01 (Poon & Hong, 2003). To avoid repetitive priming,
20
21
22 each target and its corresponding prime did not share any constituent. In total, each relation
23
24
25 condition consisted of 8 item sets. One example of the items used in Exp. 2 is shown in
26
27
28
29
30
31
32
33
34

items were included in the analysis. On average, the accuracy of responses to the prime and filler trials was 98%. In total, 6.71% of the data were excluded because children made incorrect responses to the primes.

Linear mixed model analysis

Same as Exp.1, we conducted two LMM models to investigate whether there was a priming effect of semantic relation and the role of children's morphological awareness in semantic relation processing of the expression-picture matching task of Exp.2. All the fixed and random factors in the LMM model in Exp.2 were the same as those in Exp.1. The results of the LMM model in Exp.2 are summarized in Table 2.

[Insert Table 2 here]

Different from the results of Exp.1, both the concurrent and longitudinal LMM models of Exp.2 showed that the main effect of semantic relation consistency was not significant. Overall, children showed no preference to select a relation consistent with that involved in the prime compound (i.e., POSSESSOR relation) in interpreting the ambiguous target combination.

However, the interaction between semantic relation consistency and morphological awareness was significant in both the concurrent and longitudinal models in Exp.2. The results showed that with the interference of visual similarity across primes and targets

1 removed, children with more developed morphological awareness, but not children with less
2
3
4
5 developed morphological awareness, still showed the semantic relation priming effect.
6
7

8 **Discussion**

9
10
11
12 Different from Exp.1, the relation priming effect was not significant in Exp. 2,
13
14
15
16 indicating that increased complexity of visual features indeed affected children's processing
17
18
19 of relation information. Nevertheless, the significant interaction between semantic relation
20
21
22 consistency and the scores of morphological awareness tasks in both concurrent and
23
24
25
26 longitudinal LMM models, which indicated that children with more developed morphological
27
28
29 awareness outperformed the children with less developed morphological awareness in
30
31
32 processing semantic relation information. In other words, with the interference of more
33
34
35
36 complex visual features, children with more developed morphological awareness still
37
38
39 recognized the semantic relation involved in the prime and utilized it to interpret the
40
41
42
43 subsequent target. On the other hand, children with less developed morphological awareness
44
45
46
47 showed difficulty in processing and applying the semantic relation involved in the prime.
48
49
50

51 **General discussion**

52
53
54 The current study sought to examine the role of morphological awareness in
55
56
57
58
59
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 29

1 influencing children's semantic relation processing. We tested the semantic relation
2
3
4
5 processing of children with expression-picture matching tasks and its relationship with
6
7
8 children's morphological awareness. The results revealed that consistent with our hypothesis,
9
10
11 children's morphological awareness facilitated the processing of semantic relation
12
13
14 information of novel compounds.
15
16
17
18
19

20 The results in children with more developed morphological awareness were consistent
21
22
23 with the results in adults in the previous study by Raffray et al. (2007). They were able to
24
25
26 overcome the influence of visual information and processed the implicit semantic relation
27
28
29 information. The results of Exp.2 provided further evidence to support that the relation
30
31
32 priming effect of children with more developed morphological awareness in Exp.1 was
33
34
35 attributable to processing of semantic relation information rather than visual priming.
36
37
38
39
40
41

42 However, the results of children with less developed morphological awareness were different.
43
44
45 Their performance in Exp.2 showed that they were impacted by the visual information when
46
47
48 processing novel compounds. Taken together with the findings in adults (Raffray et al., 2007),
49
50
51 our results suggest that children with good morphological awareness might have developed a
52
53
54 strategy similar to that used by adults for word acquisition, while the children with poor
55
56
57
58
59
60
61
62
63
64
65

1 morphological awareness had not.
2
3

4
5 At the same time, the significant interaction between semantic relation consistency
6
7
8
9 and morphological awareness in the concurrent and longitudinal model of Exp.1 and Exp.2
10
11
12 suggested that children's processing of the semantic relation information could be moderated
13
14
15
16 by their morphological skills. Previous study found that children could leverage their
17
18
19 understanding of the morphological structure of words when they encountered unfamiliar
20
21
22
23 complex morphological words, even in the absence of instruction (Bowers & Kirby, 2010;
24
25
26
27 Wysocki & Jenkins, 1987). Children are able to take advantage of familiar morphological
28
29
30 structure even in lexical items that had never been encountered (McCutchen & Logan, 2011).

31
32
33
34 The findings of current study extended the role of morphological awareness in word
35
36
37
38 acquisition. Children could rely on the word formation rules at morphological structure level
39
40
41
42 (e.g., subordinate structure) to infer similar rules at semantic relation level
43
44

45
46 To illustrate, children with better morphological awareness have better performance in
47
48
49 processing morphological structure information, which in turn facilitates their acquisition of
50
51
52
53 the rule that words with the same form usually share the same internal structure. If the
54
55
56
57 morphological structure information is not adequate for access to meaning, such as
58
59
60
61
62
63
64
65

1 interpreting the ambiguous compounds in the current study, children with better
2
3
4
5 morphological awareness have an ability to apply the word formation rule at a more detailed
6
7
8 structure level (i.e., semantic relation). Thus, it is possible that morphological awareness
9
10
11
12 facilitates children's development of an efficient strategy for acquiring and retaining words
13
14
15
16 (McCutchen & Logan, 2011).
17
18
19

20 As suggested by Ku and Anderson (2003), children's insights into the internal
21
22 structure of words play an important role in reading development. In light of this perspective,
23
24
25
26
27 the findings in the present study indicated that compared to children with less developed
28
29
30 morphological awareness, children with more developed morphological awareness not only
31
32
33
34
35 could better process the morphological structure of words, but also showed the ability to
36
37
38 parse more detailed internal structural information of the component morphemes, i.e.,
39
40
41
42 semantic relation information. In other words, morphological information is helpful not only
43
44
45
46 for children's acquisition of novel words, but also for their ability to categorize the words
47
48
49
50 (Kuo & Anderson, 2006). Thus, the results of the present study provided a possible
51
52
53 explanation for the underlying mechanism of the role of morphological awareness in word
54
55
56
57 learning.

63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 32

1 As for children with less developed morphological awareness (i.e., low score of the
2
3
4 morphological awareness tasks), the results of Exp.2 demonstrated that, visual features might
5
6
7
8 influence their processing of implicit semantic relation information. However, based on their
9
10 performance in Exp.1, there is a possibility that additional visual features might facilitate the
11
12 processing of implicit semantic relations, at least to some extent. The results of Exp.1 in the
13
14 current study indicated that with the extra information provided by the visual features,
15
16
17
18
19
20
21
22
23 children with poor morphological awareness could process semantic relation information as
24
25
26
27 good as the children with good morphological awareness.
28
29
30

31 It is possible that the similar visual features (e.g., the larger animal image) between
32
33
34 primes and targets may help children to realize the same implicit semantic relations between
35
36
37 them. Referring to this, providing additional visual information might be an efficient method
38
39
40
41
42 to assist children in developing the ability to process implicit information of words (i.e.,
43
44
45 morphological structure and semantic relation). For example, when children learn novel
46
47
48
49 compounds, teachers could provide corresponding pictures to visualize the inner structure of
50
51
52
53 the words. Previous studies have found that visualizing the content for reading could improve
54
55
56
57 children's literacy performance (Glenberg et al., 2004). Taken together with our findings,
58
59
60
61
62
63
64
65

1 visualization might facilitate children, especially those with poor morphological awareness,
2
3
4
5 to discover the similarity in morphological structure and semantic relations between words.
6
7

8 The current study is among the first to demonstrate the association between
9
10
11
12 morphological awareness and the processing of semantic relations among Chinese children.
13
14
15
16 Although we provided empirical evidence that children with good morphological awareness
17
18
19
20 showed a better ability in processing semantic relation information, only third grade students
21
22
23
24 were included as participants in the present study. In order to investigate the relationship
25
26
27
28 between morphological awareness and semantic relation processing from a development
29
30
31 point of view, children with different ages should be considered in the future. Furthermore,
32
33
34
35 we only investigated the processing of semantic relation information in one morphological
36
37
38
39 structure, namely subordinate structure. There are other morphological structures in Chinese
40
41
42
43 compounds, such as coordinative, subject-predicate, and verb-object. The processing of
44
45
46
47 semantic relation information under these morphological structures may be influenced by the
48
49
50
51 level of morphological awareness in different ways. These issues can be further addressed in
52
53
54
55
56
57 the future in order to gain a comprehensive understanding of the relationship between
58
59
60
61
62
63
64
65 morphological awareness and semantic relation processing.

1 Despite these limitations, the present study was among the first to investigate the
2
3
4
5 relationship between morphological awareness and semantic relation processing. Different
6
7
8 from most previous studies related to the association between morphological awareness and
9
10
11
12 word processing in children (e.g., Li et al., 2002; Ku & Anderson, 2003), the current study is
13
14
15 original in focusing on the detailed internal semantic relations in word processing when
16
17
18
19 examining the role of morphological awareness. The findings in the present study help us
20
21
22
23 better understand the mechanism underlying the association between morphological
24
25
26
27 awareness and word reading. One possible explanation, as supported by the current findings,
28
29
30
31 is that morphological awareness can facilitate the processing of semantic relation information,
32
33
34
35 and in turn help children understand the meaning of the whole compound by parsing the
36
37
38
39 relations between the component morphemes. The findings in the present study have some
40
41
42
43 implications. First, besides the morphological structure, the semantic relation information
44
45
46
47 may also be highlighted in the future in applying the analytical approach in helping children
48
49
50
51 to improve their reading performance. Intervention studies conducted in both alphabetic
52
53
54
55 languages (e.g., Carlisle, 2010; Kirk & Gillon, 2007) and Chinese (e.g., Shu, McBride-Chang,
56
57
58
59 Wu, & Liu; 2006; Chow, McBride-Chang, Cheung, & Chow, 2008) have evidenced the
60
61
62
63
64
65

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN 35

effectiveness of training on morphological awareness in improving children's literacy performance. The training effect may be further enhanced by incorporating semantic relation information into the intervention. Second, considering the influence of visual features on processing of semantic relation information, appropriate use of visual cues in instruction may help improve children's acquisition of implicit information (i.e., morphological structures and semantic relations).

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN

		Relation	
Prime	POSSESSOR	DESCRIPTOR	
	鯊碗 (shark bowl)	兔巾 (rabbit scarf)	
			
Target	豬書 (pig book)		
			

Figure 1. Sample stimuli for Exp. 1.

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG CHINESE CHILDREN

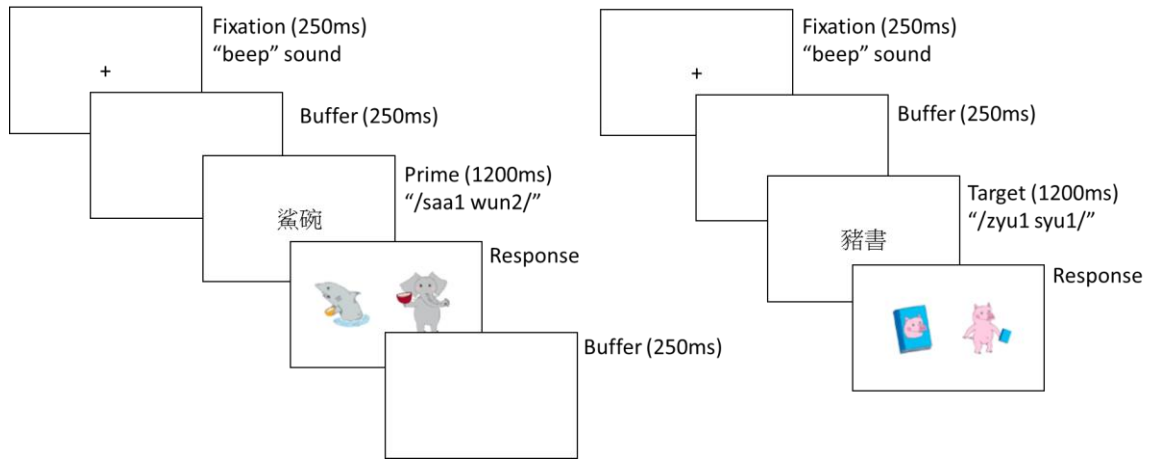

Figure 2. The procedure of Exp. 1.

THE PROCESSING OF SEMANTIC RELATION INFORMATION AMONG
CHINESE CHILDREN

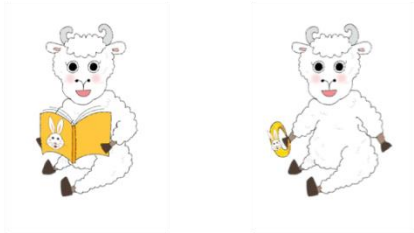

Relation		
Prime	POSSESSOR	DESCRIPTOR
	羊環 (sheep wistband) 	蝶扇 (butterfly fan) 
Target	鼠箱 (rat box) 	

Figure 3. Sample stimuli for Exp. 2.

Table 1

Linear mixed model estimates of fixed effects of Exp.1

	Variables	Beta	Standard error	<i>t</i> -value	<i>p</i>
Concurrent model	Semantic relation consistency	.06	.004	16.48	< .01
	Morphological awareness (Time 2)	.003	.01	.26	.79
	Semantic relation consistency × Morphological awareness (Time 2)	.008	.003	3.28	.001
	Age	-.003	.02	-.21	.83
	Non-verbal intelligence	.04	.02	2.42	.02
	Chinese character reading (Time 2)	.002	.02	.12	.91
	Phonological awareness (Time 2)	.02	.02	1.22	.22
	Item complexity	-.001	.001	-.80	.42
	Item frequency	-.0001	.001	-.09	.93
Longitudinal model	Semantic relation consistency	.06	.004	15.83	< .01
	Morphological awareness (Time 1)	.01	.01	1.23	.22

Semantic relation consistency ×	.01	.002	4.64	< .01
Morphological awareness (Time 1)				
Age	-.003	.02	-.21	.83
Non-verbal intelligence	-.03	.02	1.88	.06
Chinese character reading (Time 1)	.02	.02	1.14	.26
Phonological awareness (Time 1)	.01	.02	.64	.52
Item complexity	-.0003	.001	-.26	.80
Item frequency	-.0002	.002	.16	.88

Table 2

Linear mixed model estimates of fixed effects of Exp.2

	Variables	Beta	Standard error	<i>t</i> -value	<i>p</i>
Concurrent model	Semantic relation consistency	-.006	.006	-.90	.45
	Morphological awareness (Time 2)	-.002	.01	-.17	.83
	Semantic relation consistency × Morphological awareness (Time 2)	.008	.003	2.34	.02
	Age	-.02	.02	-1.01	.31
	Non-verbal intelligence	.08	.02	3.88	< .01
	Chinese character reading (Time 2)	-.01	.02	-.59	.56
	Phonological awareness (Time 2)	-.02	.02	-1.11	.27
	Item complexity	.002	.002	1.11	.26
	Item frequency	.001	.006	.23	.81
Longitudinal model	Semantic relation consistency	.004	.006	.68	.50
	Morphological awareness (Time 1)	.01	.02	.70	.48

Semantic relation consistency ×	.01	.004	2.57	.01
Morphological awareness (Time 1)				
Age	-.02	.02	-1.14	.26
Non-verbal intelligence	.07	.02	3.29	.001
Chinese character reading (Time 1)	-.01	.02	-.59	.56
Phonological awareness (Time 1)	-.003	.02	-.18	.86
Item complexity	.002	.002	1.15	.28
Item frequency	.001	.006	.17	.87
